

CS321 Languages and Compiler Design I Winter 2012 Lecture 4

LEXICAL ANALYSIS EXAMPLE

Pattern	Token	Attribute
if	IF	
else	ELSE	
print	PRINT	
then	THEN	
:=	ASSIGN	
= or < or >	RELOP	enum
letter followed by letters or digits	ID	symbol
digits	NUM	int
chars between double quotes	STRING	string

Convert source file characters into token stream.

Remove content-free characters (comments, whitespace, ...)

Detect lexical errors (badly-formed literals, illegal characters, ...)

Output of lexical analysis is input to syntax analysis.

Could just do lexical analysis as part of syntax analysis.

But choose to handle separately for better modularity and portability, and to allow make syntax analysis easier.

Idea: Look for **patterns** in input character sequence, convert to **tokens** with **attributes**, and pass them to parser in **stream**.

PSU CS321 W'12 LECTURE 4 © 1992-2012 ANDREW TOLMACH

Source code:

Lexeme	Token	Attribute
if	IF	
x	ID	"x"
>	RELOP	GT
17	NUM	17
then	THEN	
count	ID	"count"
:=	ASSIGN	
2	NUM	2
else	ELSE	
print	PRINT	
"bad!"	STRING	"bad!"

A **token** describes a **class** of character strings with some distinguished meaning in language.

- May describe **unique** string (e.g., IF, ASSIGN)
- or set of possible strings, in which case an **attribute** is needed to indicate which.

(Tokens are typically represented as elements of an **enumeration**.)

A **lexeme** is the string in the input that actually matched the pattern for some token.

Attributes represent lexemes converted to a more useful form, e.g.,:

- strings
- symbols (like strings, but perhaps handled separately)
- numbers (integers, reals, ...)
- enumerations

Whitespace (spaces, tabs, new lines, ...) and **comments** usually just disappear (unless they affect program meaning).

HAND-CODED SCANNER (IN PSEUDO-JAVA)

```
Token getToken() {
  while (true) {
     char c = read();
     if (c is whitespace)
       ignore it;
     else if (c is digit) {
        int n = 0;
        do \{n = n * 10 + (c- '0');
            c = read(); }
        until (c not a digit);
        unread(c);
        return new Token(NUM,n);
     } else if (c is alpha) {
        String s = "";
        do { s = s + c;
             c = read();
        } until (c is not an alphanumeric);
        unread(c);
        return new Token(ID,S);
    } else ... } }
```

STREAM INTERFACE

Could convert entire input file to list of tokens/attributes.

But parser needs only one token at a time, so use **stream** instead:

Pros and Cons of Hand-coded Scanners

Efficient!

But easy to get wrong!

Note intermixed code for input, output, patterns, conversion.

Hard to specify! (esp. patterns).

FORMALIZING PATTERN DESCRIPTIONS

Ex.: "An identifier is a letter followed by any number of letters or digits."

• Exactly what is a letter?

• Exactly what is a digit?

$$DIGIT \rightarrow \ \ 0 \ | \ 1 \ | \ 2 \ | \ 3 \ | \ 4 \ | \ 5 \ | \ 6 \ | \ 7 \ | \ 8 \ | \ 9$$

• How can we express "letters or digits" ?

$$L_OR_D \rightarrow LETTER \mid DIGIT$$

• How can we express "any number of"?

$$L_OR_DS \rightarrow L_OR_D^*$$

How can we express "followed by"?

$$IDENTIFIER \rightarrow LETTER L_OR_DS$$

LANGUAGES: SOME PRELIMINARY DEFINITIONS

- An alphabet is a set of symbols (e.g., the ASCII character set).
- A **language** over an alphabet is a set of strings of symbols from that alphabet.
- ullet We write ϵ for the **empty string** (containing zero characters); some authors use λ instead.
- If x and y are strings, then the **concatenation** xy is the string consisting of the characters of x followed by the characters of y.
- If L and M are languages, then their **concatenation** $LM = \{xy \mid x \in L, y \in M\}.$
- The **exponentiation** of a language L is defined thus: $L^0 = \{\epsilon\}$, the language containing just the empty string, and $L^i = L^{i-1}L$ for i > 0.

REGULAR EXPRESSIONS

A **regular expression (R.E.)** is a concise formal characterization of a **regular language** (or **regular set**).

Example: The regular language containing all **identifiers** is described by the regular expression

where "|" means "or" and " e^* " means "zero or more copies of e."

Regular languages are one particular kind of formal languages.

1

REGULAR EXPRESSIONS AND LANGUAGES

Each **R.E.** over an alphabet Σ denotes a **regular language** over Σ , according to the following **inductive definition**:

Base rules:

- The R.E. ϵ denotes $\{\epsilon\}$.
- For each $a \in \Sigma$, the R.E. a denotes $\{a\}$, the language containing the single string containing just a.

Inductive rules: If the R.E. R denotes L_R and the R.E. S denotes L_S , then

- $R \mid S$ denotes $L_R \cup L_S$.
- $R \cdot S$ (or just RS) denotes $L_R L_S$.
- ullet R^* denotes $L_R^* = \bigcup_{i=0}^\infty L^i$, the "Kleene closure" (the concatenation of zero or more strings from L_R).

Also: (R) denotes L_R .

Precedence rules: () before * before · before |.

REGULAR EXPRESSIONS

Examples (over alphabet {a, b})

```
\begin{array}{ll} a^* & \text{zero or more a's} \\ (a \mid b)^* & \text{all strings of a's and b's of length} \geq 0 \\ (a^*b^*)^* & \text{ditto} \\ (aa \mid ab \mid ba \mid bb)^* & \text{all strings of a's and b's of even length} \end{array}
```

Counterexamples (Not every language is regular!)

- $\bullet \; \{\mathtt{a}^n\mathtt{b}^n \mid n \geq 0\}$
- Set of strings over {(,)} such that parentheses are properly matched.

Implication: regular languages can't be used to describe arithmetic expressions.

R.E.'s are everywhere in command-line programming tools

grep, Perl, shell commands, etc.

SPECIFYING LEXICAL ANALYZERS

Can define lexical analyzer via list of pairs:

(regular expression, action)

where **regular expression** describes token pattern (maybe using auxiliary regular definitions),

and **action** is a piece of code, parameterized by the matching lexeme, that returns a (token,attribute) pair.

Example

(digit ⁺ ,	{return new	<pre>Token(NUM,parseInt(lexeme));]</pre>	})
(alpha(alpha digit)*,	{return new	<pre>Token(ID,lexeme);}</pre>)
(space tab newline,	{})
(,)
(,)
(,)

So R.E'.s can help us **specify** scanners.

But can they help us generate running code that does pattern matching?

PSU CS321 W'12 LECTURE 4 © 1992-2012 ANDREW TOLMACH

REGULAR DEFINITIONS

Give names to R.E.'s and then use these as a shorthand.

Note that id and keywords have overlapping patterns.

- Must avoid recursive definitions!
- Example of "syntactic sugar"

Examples:

```
id
              → letter (letter | digit)*
                    digit (digit)*
                                                               or this shorthand: digit+
num
if
                                                                          (not too useful!)
                    if
then
                    then
                    < | > | <= | >= | =
                                                                 or: <(\epsilon \mid =) \mid >(\epsilon \mid =) \mid =
relop
assgn
                    "(nonquote)*"
string
                    a | b | ... | z | A | ... | Z
                                                          or this shorthand: [a-zA-Z]
letter
                   0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
                                                               or this shorthand: [0-9]
digit
            \rightarrow letter | digit | ! | $ | \% | \ldots
nonquote
```
