CS321 Languages and Compiler Design I Winter 2012 Lecture 6

SYNTAX ANALYSIS

Specify legal program formats using context-free grammar (CFG)

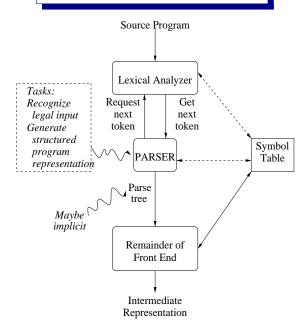

- Use Backus-Naur Form (BNF) as notation.
- Gives precise, readable specification.
- Many CFG's have efficient parsers.
- Parser **recognizes** syntactically legal programs and **rejects** illegal ones.

Successful parse also captures **hierarchical** structure of programs (expressions, blocks, etc.).

• Convenient representation for further semantic checking (e.g., types) and for code generation.

We can use another program generator (e.g., yacc or CUP) to generate parser automatically from grammar.

SYNTAX ANALYSIS (PARSING)

GRAMMARS

A Context-free Grammar is described by a set of productions (also called rewrite rules), e.g.:

$$stmt \rightarrow if expr then $stmt else stmt$$$

$$expr \rightarrow expr + expr | expr * expr$$

 $| (expr) | -expr | id$

Grammars contain **terminals** (\equiv **tokens**) (e.g. if,+,id) and **non-terminals** (e.g., *expr*,*stmt*).

Grammars have a distinguished **start symbol** (ordinarily listed first, e.g., *stmt*).

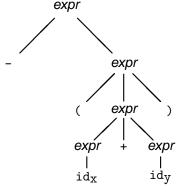

The language **generated** by a grammar is the set of **sentences** (strings) of terminals that can be **derived** by repeated application of productions, beginning with **start symbol**.

ullet We write L(G) for the language generated by grammar G.

Parse Trees

A **parse tree** is the graphical representation of a derivation.

Example tree for derivation of sentence $-(id_X + id_y)$:

Each application of a production corresponds to an **internal** node, labeled with a **non-terminal**.

Leaves are labeled with **terminals**, possibly with attributes.

The derived sentence is found by reading leaves left-to-right.

DERIVATIONS (2)

We can define **rightmost derivation** analogously:

$$\begin{array}{rcl} expr & \Rightarrow & - \; expr \\ & \Rightarrow & -(expr) \\ & \Rightarrow & -(expr + \; expr) \\ & \Rightarrow & -(expr + \; id_y) \\ & \Rightarrow & -(id_X \; + \; id_y) \end{array}$$

Every parse tree has a **unique** leftmost derivation and a **unique** rightmost derivation.

(These are usually, but not necessarily, different.)

Can "linearize" a parse tree into a sequence of one-step derivations.

Example:

$$\begin{array}{rcl} expr & \Rightarrow & - \; expr \\ & \Rightarrow & -(expr) \\ & \Rightarrow & -(expr + \; expr) \\ & \Rightarrow & -(\mathrm{id}_X \; + \; \mathrm{expr}) \\ & \Rightarrow & -(\mathrm{id}_X \; + \; \mathrm{id}_Y) \\ \text{or} \\ expr & \stackrel{*}{\Rightarrow} & -(\mathrm{id}_X \; + \; \mathrm{id}_Y) \end{array}$$

Here \Rightarrow is pronounced "derives" and $\stackrel{*}{\Rightarrow}$ is pronounced "derives in zero or more steps."

This example gives a **leftmost derivation**, i.e., at each step, the leftmost non-terminal is replaced.

AMBIGUITY

BUT a given **sentence** in L(G) can have more than one parse tree. Grammars G for which this is true are called **ambiguous**.

Example: with our grammar, the sentence

$$id_X + id_y * id_Z$$

has two parse trees:

We might think that the left tree is the "correct" one, but nothing in the grammar says this.

RESOLVING AMBIGUITIES

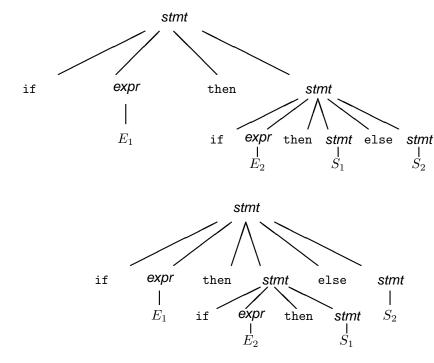

Ambiguous grammars can be a significant problem in practice, because we rely on the parse tree to capture the basic structure of a program.

To avoid the problems of ambiguity, we can try to:

- Rewrite grammar
- Use "disambiguating rules" when we implement parser for grammar.

When using these techniques, we must be careful not to change the language generated by our grammar. And often, we must do extra work to make sure that the (unique) parse trees we end up with are the ones we wanted.

A CLASSIC AMBIGUITY: THE "DANGLING ELSE"

Suppose we want else clauses to be optional in if statements. Here's a possible grammar:

```
stmt \rightarrow if expr then stmt | if expr then stmt else stmt | ...
```

Given this grammar, a statement of the form

if
$$E_1$$
 then if E_2 then S_1 else S_2

has two possible parse trees...

1

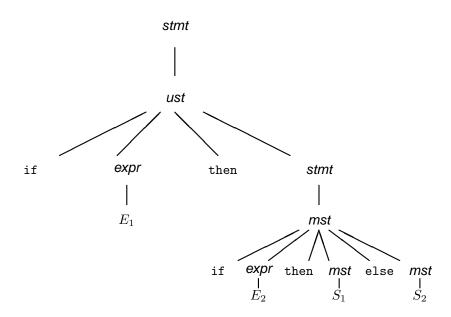

RESOLVING AMBIGUITY BY REWRITING GRAMMAR

For most languages, we want the first tree (else goes with most recent then), but grammar is ambiguous.

Solution: rewrite grammar using new non-terminals *mst* ("matched statement") and *ust* ("unmatched statement").

Now only one parse is possible.

Assuming S_1 , S_2 are not unmatched if statements, we get...

STANDARD PRECEDENCE AND ASSOCIATIVITY

The "usual" rules (based on common usage in written math) give the following precedences, highest first:

- (unary minus)

↑ (exponentiation)

* /

+ -

All the binary operators are left-associative except exponentiation (\uparrow).

Note that these rules are just a matter of **convention**; a programming language designer might choose different ones.

We can handle precedence/associativity information as "side-conditions" to ambiguous grammar when building a parser (by hand or via a parser generator).

AMBIGUITY IN ARITHMETIC EXPRESSIONS

A grammar such as

is ambiguous about order of operations.

Want to define

- Precedence which operation is done first ("binds more tightly") ?
- Associativity is

 $X op_1 Y op_2 Z$

equivalent to

(X op_1 Y) op_2 Z (left-associativity)

or to

 $X op_1$ (Y op_2 Z) (right-associativity)

assuming op_1 and op_2 have same precedence?

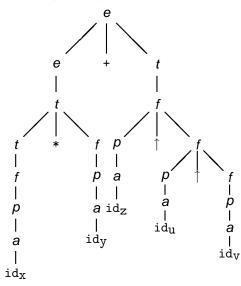

PSU CS321 W'12 LECTURE 6 © 1992-2012 ANDREW TOLMACH

REWRITING ARITHMETIC GRAMMARS

Can build precedence/associativity into grammar using extra non-terminals, each corresponding to a separate level of precedence:

```
atom 
ightarrow (expr) \mid id
primary 
ightarrow -primary \mid atom
factor 
ightarrow primary \uparrow factor \mid primary
term 
ightarrow term * factor \mid term / factor \mid factor
expr 
ightarrow expr + term \mid expr - term \mid term
```

Example: $id_X * id_V + id_Z \uparrow id_U \uparrow id_V$

PSU CS321 W'12 LECTURE 6 © 1992-2012 ANDREW TOLMACH

ISSUES WITH EBNF

Must be careful not to **change** the generated language accidentally when going between EBNF and BNF.

Also, note that EBNF grammar given in example is ambiguous because we've lost the associativity information present in the BNF version (even though both generate same language).

Often, a language's grammar will be given in ambiguous EBNF tegether with separate informal specifications that resolve the ambiguities.

Various semi-standard extensions to BNF are often used in language manuals.

They allow grammar specifications to avoid explicit recursion and ϵ -productions, by adding **optional** symbols, **repetition**, and **grouping**.

```
[a]
             means a \mid \epsilon
{a}
             means \epsilon \mid a \mid aa \mid \dots
(a \mid b)c means ac \mid bc
```

To avoid confusion between new meta-symbols and terminals, we often enclose the latter in single quotes:

Example:

```
'(' expr')' | id
atom
primary
             -primary | atom
factor
             primary { ↑ primary }
              { factor ( * | / ) } factor
term
                term ( + | - ) } term
expr
```

PSU CS321 W'12 LECTURE 6 © 1992-2012 ANDREW TOLMACH

PROPERTIES OF CFG'S

Any regular language can be described by a CFG.

Example: (a|b)*abb

$$egin{array}{lll} A_0 &
ightarrow & \mathtt{a} A_0 \mid \mathtt{b} A_0 \mid \mathtt{a} A_1 \ A_1 &
ightarrow & \mathtt{b} A_2 \ A_2 &
ightarrow & \mathtt{b} A_3 \ A_3 &
ightarrow & \epsilon \end{array}$$

But we don't use CFG's for lexical analysis, because it's overkill.

Regular expressions are:

- easier to understand
- shorter
- always lead to efficient analyzers

Any CFL can be parsed by a computer program, but only some CFL's can be parsed efficiently.

We'll study both "bottom-up" and "top-down" parsing methods.

CFG'S CAN'T DO EVERYTHING

Not every language is a CFL.

Example: $L = \{wcw \mid w \in (a \mid b)^*\}$ is not CF.

- ullet L abstracts idea of variable declaration before use.
- So "semantic" analysis (type-checking) uses additional (mostly ad-hoc) techniques.
