CS321 Languages and Compiler Design I
Fall 2010
Lecture 16
OBJECT-ORIENTED PROGRAMMING

- A set of programming techniques.
- An architectural style.
- A modeling approach.

What is it?
- Program is structured as collection of objects interacting via explicit interfaces.
- Objects encapsulate state.
- Objects are (usually) grouped into classes that share common interface.
- Classes are related by inheritance.
- Operations in interface use dynamic binding.
**WHY USE OBJECTS?**

- The **real world** can often be modeled by a collection of interacting objects. Classic examples: simulation, user interfaces. But OOP can be used for any kind of programming task.

- Building programs around objects allows model, specification, program to **share** common framework.

- A data object can be added or changed without affecting other existing objects, leading to easier **maintenance**. (Compare top-down procedural design.)

- Data abstraction/encapsulation enables easier **re-use** of code.
Objects vs. ADT’s

Classes are a lot like ADT definitions, and objects are a lot like values of the ADT. What’s the difference?

- In most OO languages, there is a superficial syntactic difference: each function defined for an object takes the object itself as an implicit argument.

  ```
  s.add(x) ; OO style
  Set.add(s,x) ; ADT style
  ```

- There is a corresponding change in metaphor: instead of applying functions to values, we talk of “sending messages to objects.”

- OO languages have some form of inheritance and dynamic binding.

Important OO Languages: Simula 67, Smalltalk, C++, Java, C#

Differences among languages: Are there types? Is everything an object?

(Note: Some OO languages, e.g., Self, JavaScript, have objects but no classes.)
Often one object class differs only slightly from another one, perhaps previously defined.

The similarity may be:

- in how the classes can be used; and/or
- in how the classes are implemented.

To avoid having to define a class twice, we might like to inherit most of the definition of one class from the other, possibly making just a few alterations. If class B inherits from class A, we say B is a subclass of A, and A is a superclass of B. This generalizes to an inheritance hierarchy among different classes.

At least two kinds of inheritance notions are useful, depending on the kind of similarity we are trying to take advantage of.
We’ve already seen **subtyping** (inheritance of specification), which is relevant where one class has similar external **behavior** (available operations) to the another. Subtyping usually expresses a conceptual “is-a” relationship between the concepts represented by the classes.

For example, in a GUI, we might manipulate “lines,” “text,” and “bitmaps,” all of which are conceptually a specialized kind of “display object.” Thus all should respond appropriately to messages like “display yourself” or “translate your screen origin.”

Recall key idea: if B is a subclass of A, should be able to use a B instance wherever an A instance is wanted. (Not vice-versa, since Bs may be able to do things that As cannot.) This is sometimes called “simulation.”

Note that the implementations of these operators may differ widely from one subclass to another, and might not be implemented in the common superclass at all.
abstract class DisplayObject extends Object {
    abstract void draw();
    abstract void translate(int d_x, int d_y);
}

class Line extends DisplayObject {
    int x0,y0,x1,y1; // coordinates of endpoints
    Line (int x0,int y0,int x1, int y1 {
        this.x0 = x0; this.y0 = y0; this.x1 = x2; this.y1 = y1;
    }
    void translate (int d_x, int d_y) {
        x0 += d_x; y0 += d_y;
        x1 += d_x; y1 += d_y;
    }
    void draw () {
        moveto(x0,y0);
        drawto(x1,y1);
    }
}
class Text extends DisplayObject {
    int x,y;   // coordinates of origin
    String s;  // text contents
    Text(int x, int y, String s) {
        this.x = x; this.y = y; this.s = s;
    }
    void translate (int d_x,int d_y) {
        x += d_x; y += d_y;
    }
    void draw () {
        moveto(x,y);
        write(s);
    }
}

ArrayList<DisplayObject> v = new ArrayList();
v.add (new Line(0,0,10,10));
v.add (new Text(5,5,"hello"));
for (int i = 0; i < v.size(); i++) {
    DisplayObject d = v.get(i);
    d.draw();
}
Inheritance of Implementation

Alternatively, we may have two classes whose implementations are very similar.

Then we’d like one class to inherit its implementation from the other, to avoid writing the same code twice.

Example: Could handle common code for translation in the superclass.

Note: In general, A can inherit implementation from B even when the conceptual object represented by A is not a specialization of that represented by B.
Java Implementation Inheritance Example

We would like to re-use the same translate code for all subclasses of DisplayObject.

We can do this using implementation inheritance, but note that a little bit of code redesign is required.

```java
abstract class DisplayObject extends Object {
    int x0, y0; // coordinates of object origin
    DisplayObject(int x0, int y0) {
        this.x0 = x0; this.y0 = y0;
    }
    abstract void draw();
    void translate(int d_x, int d_y) {
        x0 += d_x; y0 += d_y;
    }
}
```
class Line extends DisplayObject {
    int v_x, v_y; // vector to other endpoint
    Line(int x0, int y0, int x1, int y1) {
        super(x0, y0); this.v_x = x1 - x0; this.v_y = y1 - y0;
    }
    void draw () {
        moveto(x0, y0);
        drawto(x0 + v_x, y0 + v_y);
    }
}

class Text extends DisplayObject {
    String s;
    Text(int x0, int y0, String s) {
        super(x0, y0); this.s = s_arg;
    }
    void draw () {
        moveto(x0, y0);
        write(s);
    }
}
In particular, we often want to extend an existing system with new features, changing existing code as little as possible. Try to do this by adding a new object class that inherits most of its functionality from an existing class, but implements its own distinctive features.

The key idea here is that calls are always dispatched to the original receiving object, so that superclass code can access functionality defined in the subclasses.

Example: Consider adding a translate_and_draw function for all display objects.
abstract class DisplayObject extends Object {
    int x0, y0; // coordinates of object origin
    DisplayObject(int x0, int y0) {
        this.x0 = x0; this.y0 = y0;
    }
    abstract void draw();
    void translate(int d_x, int d_y) {
        x0 += d_x; y0 += d_y;
    }
    void translate_and_draw(int d_x, int d_y) {
        translate(d_x, d_y);
        draw();
    }
}

ArrayList<DisplayObject> v = new ArrayList();
v.add(new Line(0,0,10,10));
v.add(new Text(5,5,"hello");
for (int i = 0; i < v.size(); i++) {
    DisplayObject d = v.get(i);
    d.translate_and_draw(1,1);
}
Sometimes we want a new subclass to **override** the implementation of a superclass function. Again, the rule that all internal messages go to the original receiver is essential here, to make sure most-specific version of code gets invoked.

Example: Add new `bitmap` object, with its own version of `translate`, which scales the argument.
class Bitmap extends DisplayObject {
    int sc;       // scale factor
    boolean[] b;  // bitmap
    Bitmap(int x0, int y0, int sc, boolean[] b) {
        super(x0_arg * sc,y0_arg * sc);
        this.sc = sc; this.b = b;
    }
    void translate (int d_x,int d_y) {
        x0 += x0 + (d_x * sc);
        y0 += y0 + (d_y * sc);
    }
    void draw () {
        moveto(x0,y0);
        blit(b);
    }
}

An alternative way to implement translate is using the super pseudo-variable:

    void translate (int d_x, int d_y) {
        super.translate(d_x * sc, d_y * sc);
    }
Often we’d like to use both subtyping and implementation-based inheritance, but the superclasses we want for these purposes may be different.

For example, suppose we want to define new kind of display object, called a DisplayGroup, whose values are collections of other display objects that can be translated or drawn as a unit. (This allows us to construct pictures in hierarchies.)

We want to be able to insert and retrieve the elements of a group just as for objects of the Java library class ArrayList, using add, get, size, etc.

For subtyping purposes, our group class should clearly be a subclass of DisplayObject, but for implementation purposes, it would be very convenient to make it a subclass of ArrayList.

Which should we pick?
Multiple Inheritance and Interfaces

Some languages (e.g. C++) permit multiple inheritance to handle this problem. But multiple inheritance can have confusing semantics, and supporting it can cost some runtime efficiency.

Java has only single inheritance, but it also has a notion of interfaces; these are like abstract class descriptions with no variables or method implementations at all, and are just the thing for describing subtyping.

So in Java, we could define an interface Displayable rather than the abstract class DisplayObject, and make DisplayGroup a subclass of ArrayList that implements Displayable.

```java
interface Displayable {
    void translate(int d_x, int d_y);
    void draw();
}
```
class Line implements Displayable {
    int x0,y0,x1,y1; // coordinates of endpoints
    Line (int x0,int y0,int x1,int y1) { ... }
    public void translate (int d_x, int d_y) { ... }
    public void draw () { ... }
}

class DisplayGroup extends java.util.ArrayList<Displayable> implements Displayable {
    public void translate(int d_x, int d_y) {
        for (int i = 0; i < this.size(); i++) {
            Displayable d = this.get(i);
            d.translate(d_x,d_y);
        }
    }
    public void draw () {
        for (int i = 0; i < size(); i++) {
            Displayable d = this.get(i);
            d.draw();
        }
    }
}
DisplayGroup d = new DisplayGroup();
d.add(new Line(1,2,3,4));  d.add(new Line(4,5,6,7));
d.translate(100,200); d.draw();
Another approach would be to define `DisplayGroup` as a subclass of `DisplayObject` using an `ArrayList` field to hold the group contents. This is sometimes called delegation. But then we have to redefine all the (useful) `ArrayList` methods explicitly (and boringly) for `DisplayGroup`, and pay the cost of extra method calls.

```java
class DisplayGroup extends DisplayObject {
    ArrayList<DisplayObject> contents;
    DisplayGroup() {
        contents = new ArrayList<DisplayObject>();
    }
    boolean add(DisplayObject d) {
        return contents.add(d);
    }
    DisplayObject get(int index) {
        return contents.get(index);
    }
    int size() {
        return contents.size();
    }
}
```
