

Why bother with formal semantics?

Want a precise description of language behavior that can be used by programmer and implementor.

Formal semantics gives a machine-independent reference for **correctness** of implementations.

Can be used to prove properties of languages.

- E.g., **Security** property: a well-typed program cannot “dump core” at runtime.

May improve language design by encouraging “cleaner” semantics (much as BNF aided language syntax design).

3

Semantics of Programming Languages

Semantics = “Meaning”

Programming language semantics describe **behavior** of a language (rather than its **syntax**).

All Languages have **informal** semantics:

- e.g., “This expression is evaluated by evaluating the argument expressions left-to-right to obtain actual parameter values, and then executing the function procedure specified by ID with its formal parameters bound to the actual parameter values.” (PCAT manual)
- Usually in English; imprecise; assumes implicit knowledge.

Idea of **formal** semantics:

- Describe behavior in terms of a **formalism**.
- To be useful, formalism should be simpler and/or better-understood than original language.
- Possible formalisms include:
 - logic
 - mathematical theory
 - abstract machines

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

2

Kinds of Semantics

Three traditional rough categories:

Operational Semantics

- Describe behavior in terms of an operational model, such as an **abstract machine** with a specified instruction set.

Axiomatic Semantics

- Describe behavior using a **logical system** containing specified axioms and rules of inference.

Denotational Semantics

- Describe behavior by giving each language phrase a meaning (“denotation”) in some **mathematical model**.

None of these approaches is entirely satisfactory (esp. compared to BNF approach to **syntax**).

No one “best” approach -- different forms may be useful for different purposes.

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

4

Syntax and Semantics

All these kinds of semantics are structured around language **syntax**.

Useful formalisms try to be **compositional**: the meaning of the whole is based on the meaning of the parts:

- semantics specifies meaning of primitive elements of the language (AST leaves)
- and of combining elements in the language (AST internal nodes)

Semantics can be described or computed by defining an **attribute grammar** over the language.

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

5

Operational Semantics: Simple Example

Source language AST Grammar

– Designed for easy readability

```
prog ::= stm
stm  ::= stm1 ';' stm2
stm  ::= VAR ':' exp
stm  ::= PRINT exp
exp  ::= NUM
exp  ::= VAR
exp  ::= exp1 '+' exp2
exp  ::= exp1 '*' exp2
```

– Ambiguity of the grammar doesn't matter, since it's for ASTs.

Very simplistic: no control flow, procedures, datatypes, etc.

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

7

Operational Semantics

Define behavior of language constructs by describing how they affect the state of an **abstract machine**.

Abstract machine generally defined by a **finite state** and a set of legal **state transitions** (instructions).

- Like a real machine, only simpler.

Semantics is specified by giving a **translation** from the source language to the instruction set of the abstract machine (a **compiler**!)

Machine can be high-level (complicated states and instructions) or low-level (simple states and instructions).

- The lower the machine's level, the more is **explained** by the semantics, but the more complicated they get.
- Note similarity to choice of intermediate code level.

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

6

Simple Abstract Machine

State =

- Stack of Values
- Global Environment mapping VARs to VALUES
- Current Instruction Pointer (IP)

Control = List of Instructions:

- ```
ADD, MULT
– pop top two values from stack, add/multiply them, and push result

PUSH value
– push specified value onto stack

FETCH var
– fetch value of specified var from environment and push onto stack

STORE var
– pop top value from stack and store into specified var

PRINT
– pop top value from stack and print it

HALT
```

Initially: empty stack & environment; IP at start of list.

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

8

### Syntax-Directed Semantics Definition

Use (synthesized) attributes to build list of instructions.

Notation:  $[x_1, \dots, x_n]$  is the list containing elements  $x_1, \dots, x_n$  and  $x@y$  is the concatenation of lists  $x$  and  $y$ .

**prog** ::= **stm**

**stm.p** ::= **stm.p @ [HALT]**

**stm** ::= **stm1** ';' **stm2**

**stm** ::= **VAR** ':' '=' **exp**

**stm.p** ::= **exp.p @ [STORE VAR.var]**

**stm** ::= **PRINT exp**

**stm.p** ::= **exp.p @ [PRINT]**

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

9

### Example Program

Program:  
**a** ::= **3**;  
**a** ::= **a + 2**;  
**PRINT a**

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

11

### Syntax-directed definition (continued)

**exp** ::= **NUM**

**exp.p** ::= **[PUSH NUM.num]**

**exp** ::= **VAR**

**exp.p** ::= **[FETCH VAR.var]**

**exp** ::= **exp1** '+' **exp2**

**exp.p** ::= **exp1.p @ exp2.p @ [ADD]**

**exp** ::= **exp1** '\*' **exp2**

**exp.p** ::= **exp1.p @ exp2.p @ [MULT]**

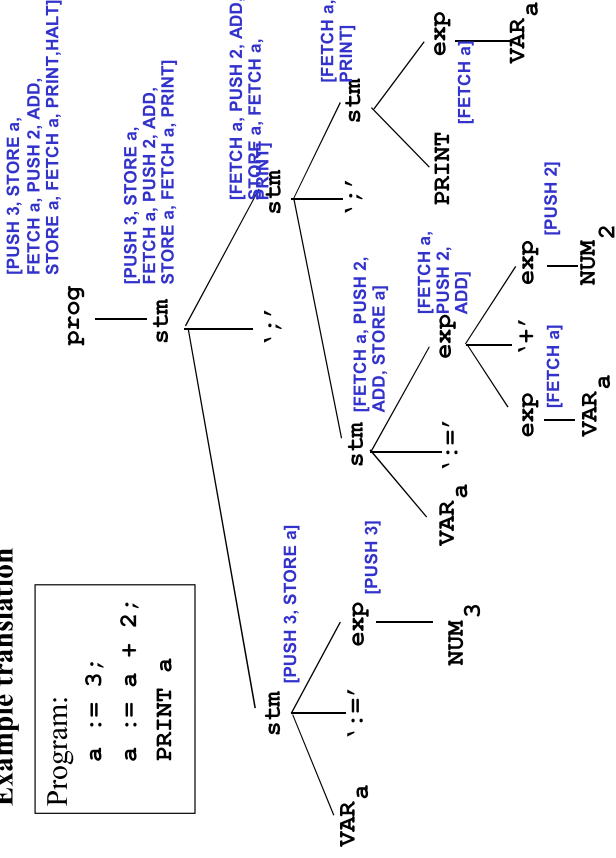

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

10

### Example translation

Program:  
**a** ::= **3**;  
**a** ::= **a + 2**;  
**PRINT a**

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

12

### Sample Execution

| Instructions | Stack | Environment |
|--------------|-------|-------------|
|              | -     | { }         |
| PUSH 3       | 3     | { }         |
| STORE a      | -     | { a = 3 }   |
| FETCH a      | 3     | { a = 3 }   |
| PUSH 2       | 3, 2  | { a = 3 }   |
| ADD          | 5     | { a = 3 }   |
| STORE a      | -     | { a = 5 }   |
| FETCH a      | 5     | { a = 5 }   |
| PRINT        | -     | { a = 5 }   |
| HALT         | -     | { a = 5 }   |

prints 5 !

12/31/04

PSU CSS322 W'05 (C) Andrew Tolmach 1997-2005

13

### Axiomatic Semantics

Describe language in terms of **assertions** about how statements affect **predicates** on program variables.

The assertion

$\{P\} S \{Q\}$

says that if **P** is true before the execution of **S**, then **Q** will be true after the execution of **S**.

Examples:

$\{y \geq 3\} x := y + 1 \{x \geq 4\}$

$\{y = 0 \wedge x = c\} \text{while } x > 0 \text{ do}$

$y := y + 1;$

$x := x - 1$

$\text{end } \{x = 0 \wedge y = c\}$

12/31/04

PSU CSS322 W'05 (C) Andrew Tolmach 1997-2005

15

### Example of Proof using Operational Semantics

Theorem: The Stack never underflows

Lemma 1: If the stack has initial size **N**, then the net effect of executing the instructions corresponding to an expression is to increase the stack size to **N+1**. Moreover, at no point during such execution is the stack size  $< N$ .

- Proof: By induction. NUM and VAR are base cases; + and \* are inductive cases.

Lemma 2: If the stack has initial size **N**, then the net effect of executing the instructions corresponding to a statement is to leave the stack at size **N**. Moreover, at no point during such execution is the stack size  $< N$ .

- Proof: By induction, with aid of Lemma 1. PRINT and := are the base cases; ; is the inductive case.

Proof of theorem: Since the program starts with a stack of size 0 and executes a single statement, Lemma 2 proves that the stack never has size  $< 0$ .

12/31/04

PSU CSS322 W'05 (C) Andrew Tolmach 1997-2005

14

### Axioms and Rules of Inference

**Axioms** are simple assertions guaranteed to be true in the language, e.g.:

$\{P[y/x]\} x := y \{P\}$

- where  $P[y/x]$  means **P** with every instance of **x** replaced by **y**.

**Rules of inference** are rules for deriving a true assertion from other true assertions, e.g.:

$\{P\} S \{Q\} \quad \{Q\} T \{R\}$

---

$\{P\} S;T \{R\}$

$\{P \wedge B\} S \{P\}$

---

$\{P\} \text{while } B \text{ do } S \{P \wedge \sim B\}$

12/31/04

PSU CSS322 W'05 (C) Andrew Tolmach 1997-2005

16

## Uses of Axiomatic Semantics

May be used for proving programs “correct”.

- I.e., given, axioms and rules of inference of the language, show that a given assertion about a given program is true.
- Example: Prove

```
{k > 0} Prog {sum = 1 + 2 + ... + k}
```

- where **Prog** is

```
 i := k; sum := k;
 while i > 1 do
 i := i - 1;
 sum := sum + i
end;
```

- Can be done by repeated application of axioms and rules.

Axiomatic methods become unwieldy in presence of side-effects and aliasing (multiple names for one storage location).

For handling real programs, automated “proof assistant” is essential.

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

17

## Denotational Semantics

Program statements and expressions denote mathematical **functions** between abstract **semantic domains**.

- In particular, the program as a whole denotes a function from some domain of inputs to some domain of answers.

Semantics are specified as a set of **denotation functions** mapping pieces of program syntax to suitable mathematical functions.

- Functions are attached to corresponding grammatical constructs using synthesized attribute grammars.

Proper definition of semantic domains is complicated subject -- we'll ignore.

Common notation:  $\lambda x. e$  is an anonymous function with argument **x** and body **e**.

$\lambda x. x+1$        $\lambda y. \text{if } y < 0 \text{ then } -y \text{ else } y$

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

19

## Example Proof of correctness in annotation form

```
{k > 0}
{k = k + ... + k ^ k > 0}
i := k;
{k = i + ... + k ^ i > 0}
sum := k;
{sum = i + ... + k ^ i > 0}
while i > 1 do
 {sum = i + ... + k ^ i > 0 ^ i > 1}
 i := i - 1;
 {sum = (i+1) + ... + k ^ i > 0}
 sum := sum + i
 {sum = i + ... + k ^ i > 0}
end;
{sum = i + ... + k ^ i > 0 ^ ~ (i > 1)}
{sum = 1 + ... + k}
```

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

18

## Denotational Semantics of Straight-line Programs

Semantic domains:

$V = \text{Int}$  (values)  
 $\text{Ide}$  (identifiers)  
 $S = \text{Ide} \rightarrow V$  (stores)  
 $\text{Exp} = S \rightarrow V$  (expressions)  
 $\text{Stm} = S \rightarrow S$  (statements)

Denotation functions (from syntactic class to semantic domain):

$I: \text{ID} \rightarrow \text{Ide}$   
 $N: \text{NUM} \rightarrow V$   
 $E: \text{exp} \rightarrow \text{Exp}$   
 $S: \text{stm} \rightarrow \text{Stm}$

Auxiliary functions:

$\text{plus}: V \times V \rightarrow V$   
 $\text{update}: (S \times \text{Ide} \times V) \rightarrow S$

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

20

### Denotation function definition

$stm \rightarrow ID := exp$   
 $stm \rightarrow stm1; stm2$   
 $S[stm] = \lambda s. S[stm2] (S[stm1] s)$   
 $exp \rightarrow NUM$   
 $E[exp] = \lambda s. N[NUM]$   
 $exp \rightarrow ID$   
 $E[exp] = \lambda s. s (I[ID])$   
 $exp \rightarrow exp1 + exp2$   
 $E[exp] = \lambda s. plus (E[exp1] s, E[exp2] s)$   
 $exp \rightarrow (exp1)$   
 $E[exp] = E[exp1]$

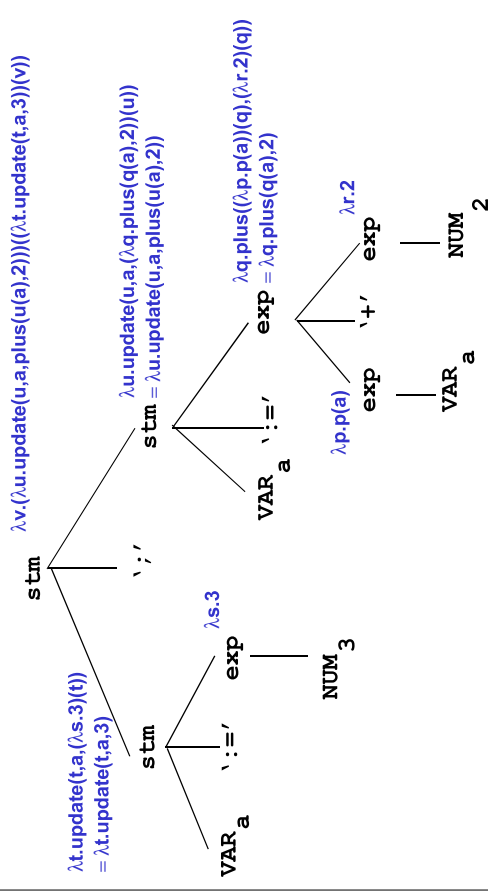

$N[NUM] = NUM.num$

$I[ID] = ID.ident$

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

21

### Calculating the denotation of a program.

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

23

### Facts about stores and updates

Definition of update:

$update = \lambda (s, id, v) .$

$\lambda id1. if id = id1 then v else s id1$

Fact A: For any  $s0, x, i$ :

$(update(s0, x, i)) x$   
 $= (\lambda id1. if x = id1 then i else s0 id1) x$   
 $= (if x = x then i else s0 x)$   
 $= i$

Fact B: For any  $s0, x, i, j$ :

$update(update(s0, x, i), x, j) =$   
 $update(s0, x, j)$

12/31/04

PSU CS322 W'05 (C) Andrew Tolmach 1997-2005

22

### Simplifying denotation:

$\lambda v. (\lambda u. update(u, a, plus(u(a), 2))) (\lambda t. update(t, a, 3)) (v)$   
 $= \lambda v. (\lambda u. update(u, a, plus(u(a), 2))) (update(v, a, 3))$   
 $= \lambda v. update(update(v, a, 3), a, plus(plus(3, 2))) (using\ Fact\ A)$   
 $= \lambda v. update(update(v, a, 3), a, 5)$   
 $= \lambda v. update(v, a, 5)$   
(using Fact B)
