1 Overview

This article documents the numerical evaluation of a well-known analytical model for transient, one-dimensional heat conduction. The physical situation is depicted in Figure 1. A sphere of uniform material is initially at a uniform temperature $T_i$. At time $t = 0$ the sphere is immersed in a stream of moving fluid at some different temperature $T_\infty$. The external surface of the sphere exchanges heat by convection. The local heat flux from the sphere to the fluid is

$$ q = h(T_s - T_\infty) $$

where $h$ is the heat transfer coefficient, and $T_s$ is the local surface temperature.

The problem is greatly simplified by assuming that the heat flux on the surface is uniform. Under this condition, $T_s = T(r_0)$ is also uniform and the temperature inside the sphere depends only on the radius, $r$, and time $t$, i.e.,
\( T = T(r, t) \). The temperature field is governed by the heat equation in spherical coordinates

\[
\frac{\partial T}{\partial t} = \frac{\alpha}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) \tag{2}
\]

where \( \alpha = k/(\rho c) \) is the thermal diffusivity of the sphere material, \( k \) is the thermal conductivity, \( \rho \) is the density, and \( c \) is the specific heat. The boundary condition on the surface is

\[
k \frac{\partial T}{\partial r} \bigg|_{r=r_0} = h(T_\infty - T_s). \tag{3}
\]

The initial condition is

\[
T(r, 0) = T_i. \tag{4}
\]

The remaining condition is that the temperature at all points in the sphere is bounded. These three conditions are sufficient to obtain a solution to Equation (2).

## 2 Analytical Solution

The analytical solution for Equation (2), subject to Equation (3), Equation (4), and the condition of bounded \( T(r, t) \) is given in several heat transfer textbooks, e.g. [1, 2]. A universal solution is obtained in terms of the dimensionless variables

\[
\theta^* = \frac{T - T_\infty}{T_i - T_\infty}, \quad r^* = \frac{r}{r_0}, \quad \text{Fo} = \frac{\alpha t}{r_0^2}. \tag{5}
\]

The dimensionless form of the boundary condition in Equation (3) is

\[
\frac{\partial \theta^*}{\partial r^*} \bigg|_{r^*=1} = \text{Bi} \theta^*_s \tag{6}
\]

where the Biot number is

\[
\text{Bi} = \frac{hr_0}{k} \tag{7}
\]

and \( \theta^*_s = (T_s - T_\infty)/(T_i - T_\infty) \). If \( \text{Bi} \ll 1 \) the internal temperature gradient is small compared to the scaled difference between the surface temperature and the fluid. In that case the temperature in the sphere is spatially uniform.

The analytical solution is the infinite series

\[
\theta^* = \sum_{n=1}^{\infty} C_n \exp(-\zeta_n^2 \text{Fo}) \frac{1}{\zeta_n r^*} \sin(\zeta_n r^*) \tag{8}
\]

where

\[
C_n = \frac{4 \left[ \sin(\zeta_n) - \zeta_n \cos(\zeta_n) \right]}{2\zeta_n - \sin(2\zeta_n)}. \tag{9}
\]
Figure 2: Plots of $f(\zeta) = 1 - \zeta \cot(\zeta) - Bi$ for $Bi = 5$ showing roots ($\ast$) and singularities ($o$) of Equation (10). Upper plot shows the range $0 \leq \zeta \leq 15$. Lower plot shows the range $0 \leq \zeta \leq 50$.

The $\zeta_n$ are the positive roots of

$$1 - \zeta_n \cot(\zeta_n) = Bi. \quad (10)$$

Equations (8) through (10) provide a compact representation of the solution. Obtaining numerical values from these formulas is a nontrivial effort except in the case where $Fo \gg 1$ when a one term approximation is sufficient. In general, at least the first few terms in the series are needed.

3 Evaluating the Solution in MATLAB

In this section, a procedure for evaluating Equation (8) is presented. The MATLAB programs, or (for long programs) the function prologues, are listed in the appendix.

3.1 Finding the Roots of Equation (10)

The first task is to find the roots, $\zeta_n$, of Equation (10) for a given $Bi$. This is a standard root-finding problem, with two important complications. First, there are an infinite number of $\zeta_n$ on the positive real line. To evaluate Equation (8) a large number of roots must be available and sorted in order of increasing $\zeta_n$. A missing root will cause erroneous evaluation of the series. The second complication is that Equation (10) has a singularity between successive roots.
3.1 Finding the Roots of Equation (10)

Figure 2 shows the function \( f(\zeta) = 1 - \zeta \cot(\zeta) - \mathrm{Bi} \) for \( \mathrm{Bi} = 5 \) in the range \( 0 \leq \zeta \leq 50 \). Note that \( f(\zeta) = 0 \) when \( \zeta \) is a root of Equation (10). The top half of Figure 2 shows \( f(\zeta) \) (for \( \mathrm{Bi} = 5 \)) in the range \( 0 \leq \zeta \leq 15 \). The roots are identified with the * symbol, and the singularities are identified by vertical dashed lines and the o symbol. The bottom half of Figure 2 shows \( f(\zeta) \) over the larger range \( 0 < \zeta \leq 50 \). As \( \zeta \) increases the spacing between roots approaches a constant, and the roots are located midway between the singularities. At small \( \zeta \) the spacing between the roots is not equal.

The \texttt{zRoots} function in Listing 1 uses the \texttt{zfun} function (Listing 2), the \texttt{bracket} function (Listing 3), and the built-in \texttt{fzero} function to find the roots of Equation (10). \texttt{fzero} is a very efficient root-finding routine, but it converges equally well to roots and singularities. The strategy used in \texttt{zRoots} is to first use \texttt{fzero} find all the roots and singularities in order of increasing \( \zeta \), and then discard the singularities. A singularity \( \hat{\zeta} \) is easily identified because \( f(\hat{\zeta}) \) is large.

The \texttt{zRoots} function can be called with two optional input arguments. The first input, \( \mathrm{Bi} \), is required. The first optional input, \( \mathrm{zmax} \), specifies the upper limit of the range of \( \zeta \) to search for roots. The second optional input, \texttt{verbose}, specifies whether the roots and singularities are printed, and whether a plot of \( f(\zeta) \) is created. For example, the top plot in Figure 2 is obtained with

\[
\texttt{>> z = zRoots(5,15,true);}
\]

5 good zeta values found in \texttt{zRoots()}
4 potential zeros are suspected to be singularities

All roots found by \texttt{fzero}
\[
\begin{array}{llll}
 k & \text{zleft} & \text{z} & \text{zright} & \text{f(z)} \\
 1 & 2.5301 & 2.5704 & 2.5904 & 3.128e-08 \\
 2 & 3.1325 & 3.1416 & 3.1928 & 6.740e+07 \\
 3 & 5.3012 & 5.3540 & 5.3614 & 2.485e-11 \\
 4 & 6.2651 & 6.2832 & 6.3253 & -1.015e+08 \\
 5 & 8.2530 & 8.3029 & 8.3133 & 3.864e-12 \\
 7 & 11.3253 & 11.3348 & 11.3855 & -1.298e-07 \\
 8 & 12.5301 & 12.5664 & 12.5904 & -1.450e+08 \\
\end{array}
\]

Good roots retained by \texttt{zRoots}
\[
\begin{array}{llll}
 n & \text{z} & \text{f(z)} \\
 1 & 2.5704 & 3.128e-08 \\
 3 & 5.3540 & 2.485e-11 \\
 5 & 8.3029 & 3.864e-12 \\
 7 & 11.3348 & -1.298e-07 \\
 9 & 14.4080 & -2.699e-07 \\
\end{array}
\]

Singularities eliminated from list of roots
\[
\begin{array}{lll}
 n & \text{zbad} & \text{f(zbad)} \\
 2 & 3.1416 & 6.740e+07 \\
 4 & 6.2832 & -1.015e+08 \\
 6 & 9.4268 & 9.273e+07 \\
 8 & 12.5664 & -1.450e+08 \\
\end{array}
\]

Note that the roots and singularities are interleaved, and that \texttt{zRoots} correctly identifies the roots.
3.2 Evaluating $\theta^*(Bi, Fo)$

In practice, a plot of the roots is not always necessary or desirable. To obtain only the $\zeta_n$ for $Bi = 5$ in the range $0 \leq \zeta \leq 50$ use

```matlab
>> z = zRoots(5, 50);
16 good zeta values found in zRoots()
15 potential zeros are suspected to be singularities
```

To facilitate manual calculation, Incropera and DeWitt [2] provide a list of the first roots of Equation (10) for a range of $Bi$ values\(^1\). The `zRootFirst` function produces a similar list of $\zeta_1$ values. There are some discrepancies in the $\zeta_1$ values created by `zRootFirst` and the list given by Incropera and DeWitt. The first few rows of output from `zRootFirst` are

```matlab
>> zRootFirst
Bi z1 f(z1)
0.01 0.1730 -2.064e-14
0.02 0.2445 -9.368e-17
0.03 0.2991 -7.494e-16 (0.2989)
0.04 0.3450 -4.517e-15
0.05 0.3854 -2.179e-15 (0.3852)
0.06 0.4217 4.857e-17
0.07 0.4551 -1.665e-16 (0.4550)
0.08 0.4860 -8.042e-14
...
```

The third column gives $f(z_1) = 1 - \zeta_n \cot(\zeta_n) - Bi$ as a check on whether $z_1$ satisfies Equation (10). The numbers in parenthesis to the right of the third column are $\zeta_1$ values from Incropera and DeWitt that differ from those created by `zRootFirst`. (Those values are not printed by the MATLAB function.) The discrepancies are small (all less than 0.07 percent) and are likely due to rounding errors in the calculations used to produce the table in the textbook by Incropera and DeWitt. The MATLAB calculations with `zRootFirst` are all in double precision\(^2\). The $z1$ values produced by `zRootFirst` all give very small residuals, and therefore are accurate.

3.2 Evaluating $\theta^*(Bi, Fo)$

Once the $\zeta_n$ are known for a given $Bi$, the dimensionless temperature is computed from Equation (8). The `Tsphere` function in Listing 5 calls `zRoots` to find the required $\zeta_n$, and then evaluates Equation (8). In other words, the user only needs to call `Tsphere` to obtain numerical values of $\theta^*$.

`Tsphere` has a number of optional input and output arguments so that it can be called in the following ways.

```matlab
T = Tsphere(Bi, Fo)
T = Tsphere(Bi, Fo, nr)
T = Tsphere(Bi, Fo, nr, verbose)
[T, r] = Tsphere(...)```

\(^1\)For large $t$ a one-term approximation to Equation (8) is sufficient.
\(^2\)Roughly fifteen decimal digits of accuracy.
3.3 Evaluating $T(r,t)$

The required inputs are $Bi$, the Biot number, and $Fo$, the Fourier number. The $Fo$ input can be a scalar or vector. The third input $nr$ is optional and specifies the number of radial positions at which $\theta^*$ is to be evaluated. If $nr$ $= 1$ then only $\theta^*$ at $r^* = 0$ is evaluated. If $nr > 1$ then $\theta^*$ is evaluated at $nr$ equally spaced values on the interval $0 \leq r^* \leq 1$.

The default output $T$ is a matrix of $\theta^*$ values. If $Fo$ is a vector, each column of $T$ corresponds to an element in $Fo$. If $nr > 1$ the rows of $T$ correspond to the $nr$ equally spaced $r^*$ values.

For example, to evaluate $\theta^*(r^*,Fo)$ at 11 uniformly spaced radial locations for $Fo = [0.1, 0.15, 0.2]$ and $Bi = 5$, use

```matlab
>> [T,r] = Tsphere(5,[0.1 0.15 0.2],11,true);
16 good zeta values found in zRoots()
15 potential zeros are suspected to be singularities
```

3.3 Evaluating $T(r,t)$

The MATLAB programs presented in this article produce dimensionless results. To solve a problem in dimensional units follow these steps:

1. Convert the dimensional inputs to $Bi$ and $Fo$.
2. Obtain the dimensionless solution $\theta^*(Bi,Fo)$.
3. Compute the temperature from the definition of $\theta^*$, viz., $T(r,t) = T_\infty + \theta^*(T_i - T_\infty)$.

3.3.1 Example

(From Incropera and DeWitt) A 5 mm radius metal sphere initially at 400°C is plunged into a water bath at 50°C. Assume that the heat transfer coefficient is 6000 W/(m²°C), the thermal conductivity of the metal is $k = 20$ W/m·K, and the thermal diffusivity of the metal is $\alpha = 6.66 \times 10^{-6}$ m²/s. Plot the variation of the centerline temperature with time for the first five seconds after...
the sphere is plunged into the water bath. Plot the radial temperature variation at $t = 0.5, 1, \text{ and } 5$ seconds.

The solution is implemented in the `sphereExample` function in Listing 6. Figure 3 shows the variation of the center temperature with time. Figure 4 shows the radial temperature variation at $t = 0.5, 1, \text{ and } 5$ seconds.

Appendix: Listings of MATLAB Codes

The MATLAB source code for the mfiles described in the article are listed on the following pages. Two of the mfiles (`zRoots` and `Tsphere`) are too long to fit on a single page. For these functions the last lines of code are omitted. The reader is encouraged to download the complete code from `http://web.cecs.pdx.edu/~gerry/epub/`. The code omitted from `zRoots` and `Tsphere` deals with optional printing of results, so the listings provided here allow the reader to study the essential parts of the calculations.
